## 1. Introduction

The scenario for the creation of LIFE Certification was configured by the need to preserve biodiversity through maintaining natural heritage and intensifying the involvement of the private sector in environmental issues. Aiming to spread the commitment to conservation more fairly, the LIFE Certification Methodology establishes a minimum performance in biodiversity conservation which is in line with each organization's size and environmental impact.

In calculating an organization's impact, The LIFE Certification Methodology takes into account the following environmental aspects: (i) Generation of Waste; (ii) Emission of Greenhouse Gases; (iii) Use of Water; (iv) Energy Consumption; and, (vi) Occupation of Area. These are used to define the organization's Biodiversity Estimated Impact Value (BEIV).

Due to the great importance of the relation between energy matrix and biodiversity conservation, and with a view to the continuous improvement of the calculation of BEIV, the LIFE Institute set up a Temporary Technical Commission for Energy (TTC – Energy) to refine the information and the practical evaluation of this relation.

The reduction of habitats and the alteration of the countryside, global warming, air quality, water availability and quality, siltation processes and soil quality are all impacts which directly or indirectly affect biodiverity and the sustaining of life on Earth.

Different sources of energy contribute in different degrees to the generation of these impacts, resulting in greater or lesser severity for biodiversity. This analysis depends on the evaluation of all the stages of the energy chain – from extraction through to its final use – considering the existent resources.

That is the work presented in this publication, which results in a single general matrix for evaluating and comparing the impact of different sources of energy. This result serves the LIFE Methodology as a reference for the evaluation of the impact of the use of the energy, and which shall be constantly improved.

An organization's decision to use one or another source of energy can represent greater care for biodiversity, and this is to be valued by LIFE Certification.

# 2. Objective of the work

The work aimed to develop a single general matrix for evaluating and comparing the impact from different sources of energy.

## 3. Methodology

The methodology adopted for this work had four stages:

- Conceptual structuring of a matrix for evaluating the impact of sources of energy
- Definition of the sources of energy and bibliographic survey of their impacts
- Evaluation of the impact of each source of energy in partial matrices
- Compilation of the results of the matrices for each source of energy in a single general matrix for evaluating and comparing energy sources' impacts

# CONCEPTUAL STRUCTURING OF A MATRIX FOR THE EVALUATION OF IMPACT OF SOURCES OF ENERGY

The structuring of the matrix took place through defining the criteria to be applied for each source of energy.

### Source of energy

the form in which the energy is found in nature (originating from natural processes of the transformation of primary sources).

The following were selected as criteria to be observed in the matrix:

### **Environmental component**

Factors which make up the environment (soil, water, atmosphere, biota) – representing the place where the impact occurs;

### **Environmental aspect**

An organization's activities, products or services that may be interacting with the environment:

### Potential impact

Alteration of the environment resulting from an organization's activities, services or products;

### **Generating action**

Action in each phase of the energy chain, responsible for generating the impact;

### Phases of the energy chain

phases which include energy extraction, conversion, distribution/storage and final uses. The phases of the energy chain determine the extent of the impacts to be considered for each source.

Considering these criteria, a matrix was structured for comparing impacts, using the Leopold Matrix (1971) as a reference, because the use of bi-dimensional criteria – a characteristic of that matrix – facilitates quantification; and, therefore, the ordering of the environmental impacts from different sources.

The following criteria were used for scoring each impact evaluated within the matrix:

### Reversibility

Evaluates the capacity to return to the original environmental conditions after the action. The classification used was: Irreversible (IRR); Reversible (REV).

### Magnitude

Evaluates the degree of de-characterization of the environmental component when submitted to the incidence of an impact. The classification adopted was: Large (LAR); Medium (MED); Small (SMA).

#### Severity

Information resulting from the combination of the analyses of Reversibility and Magnitude. The severity values were classified as:

- High (3): high/medium magnitude; irreversible or difficult to reverse
- Medium (2): high/medium magnitude; reversible
- Low (1): minimal magnitude, irrespective of its reversibility

The final score for impact was obtained by taking into account the combination of the value attributed to the "severity" criteria (1, 2, 3), with the quantity of phases of the energy chain which received this value, according to the hierarchy presented in Table 1.

| Impact | Description   |
|--------|---|
| 0      | No phase  |
| 1 - 2  | Severity 1 in one phase of the energy chain           |
| 3 - 4  | Severity 1 in more than one phase of the energy chain |
| 5 - 6  | Severity 2 in one phase of the energy chain           |
| 7 - 8  | Severity 2 in more than one phase of the energy chain |
| 9 - 10 | Severity 3 in one or more phases of the energy chain  |

The scoring of the impact always takes into account two possibilities for values for each possibility of combination, allowing subjective information to receive an appropriate final score, greater or lesser, depending on the specialists' final evaluation. This method makes it possible to differentiate the impact of sources of energy which would otherwise receive the same score.

The impacts in each phase of the energy chain were evaluated, for all of the aspects listed in each environmental component.

# DEFINITION OF THE SOURCES OF ENERGY AND THE BIBLIOGRAPHIC REVIEW OF THEIR IMPACTS

LIFE Technical Guide 1 establishes an impact index for 14 sources of energy: Biofuels (Alcohol); Biofuels (Vegetal oils and Biodiesel); Biogas; Biomass (Firewood); Biomass (Waste); Coal; Wind; Natural Gas; Geothermal; Hydroelectric; Nuclear/fission; Crude oil and oil products; Solar; and Ocean Thermal Energy Conversion.

Reviewing the sources considered, it was defined that the energy source "Ocean Thermal Energy Conversion" should be altered to energy from seawater, as this includes a wider range of technologies which produce electricity from the seawater. The review also determined that the energy source "Non-Renewable Residues" should be included. It is commonly generated by productive processes which use fossil sources. This residues has significant calorific power and can be re-used as an energy carrier.

As a result, 15 sources of energy were defined for this work: Biofuels (Alcohol); Biofuels (Oils and Biodiesel); Biogas; Biomass (Firewood); Biomass (waste); Nonrenewable Residues; Coal; Wind; Natural Gas; Geothermic; Hydroelectric; Nuclear/fission; Crude oil and oil products; Solar; and, Energy from Seawater.

Based on the determination of the phases of the energy chain, an extensive bibliographic review was undertaken, on the potential impacts related to each one of the sources of energy considered.

# EVALUATION OF THE IMPACT OF EACH SOURCE OF ENERGY IN PARTIAL MATRICES

For each one of the 15 sources of energy, an impact value was established, based on the analysis of the entire process of generation of energy.

This individual analysis for each source of energy allowed the definition of the reversibility, the magnitude and the severity for all the potential impacts linked to different generative actions in the phases of extraction, processing, conversion, storage and final use of the energy source.

All the environmental aspects listed for each one of the environmental components of water, air, soil and biota were evaluated separately. The sum of the impact value for each environmental aspect listed in these components resulted in the energy source impact index.

As a result of this stage, 15 matrices and their respective impact indexes are presented in item 4.1, this matrix relating to each source of energy studied.

## COMPILATION OF THE RESULTS OF THE MATRICES FOR EACH SOURCE OF ENERGY

The results from all 15 partial matrices were compiled into a single general matrix, making it possible to evaluate and compare the impacts of all the sources of energy studied.

The final consolidated matrix is presented in item 4.2 of this Technical Document.

## 4. Results

The partial matrices and the consolidated matrix for evaluation and comparison of the impacts from sources of energy are presented below.

## Impact Matrix: Crude oil and oil products

### **IMPACT MATRIX: SOURCES OF ENERGY**

Based on the impact matrices constructed for each source of energy, a comparative matrix was produced, listing the impact index for all 15 sources of energy evaluated. (Table 2).

Table 2: Comparative matrix for the impacts

|                               |                                 | IMPACT                   |   |                        |                         |  |                                      |                                      |                                  |                         |  |   |              |  |  |  |
